

# Decision Trees

# Decision Trees: Intuition

- Decision trees come in two flavors:
  - **Regression Trees** – the outcome is quantitative → solve similar problems than linear **regression** models
  - **Classification Trees** – the outcome is categorical → solve similar problems than **logistic**, **LDA** and **QDA** models
- Both types of trees are similar in principle in that **observations** are **split** recursively into nested **“regions”** to guide the **prediction** of new observations into one the resulting regions.
- Which model type is **better**, tree or linear? It **depends**. The 2 left diagrams below show both models when the **“true”** relationship between 2 variables is **linear**. The 2 **right** diagrams they are **not**.
